ABSTRACT

During bryological work conducted in the Sharon plane region (Israel), a colony of *Acaulon* Müll. Hal. was discovered. The plants showed morphological affinities both to *A. longifolium* Herrnst. & Heyn and *A. fontquierianum* Casas & Sérgio depending on the floras used for their identification which challenged their recognition as separate species. In order to solve this taxonomic dilemma, we conducted a detailed morphological characterization of the two species based on representative samples. The micromorphological study of vegetative, sporophytic and spore traits revealed the large overlap of range values between both species. Both species showed the characteristic combination of morphological characters, including the broadly incurved leaves with smooth cells and the 4-6 rows of inflated cells on the adaxial surface of nerve. Spore micromorphology revealed the same ornamentation pattern and the presence of 1-2 lamellar glomeruli on spore surface. Multivariate and ordination analyses based on quantitative traits did not reveal a significant separation among samples of the two species, thus opposing their recognition as separate species. As *A. fontquierianum* has priority over *A. longifolium*, the latter is thus subsumed in the synonymy of *A. fontquierianum*. The addition of new chorological data and amended taxonomy reveals that *A. fontquierianum* has a distribution area extending from the Canary Islands to the eastern Mediterranean basin. However, the scattered pattern suggests its known distribution is largely incomplete because of the tiny size of the plants and their ephemeral nature.

RÉSUMÉ

Sur la synonymisation de Acaulon longifolium Herrnst. & Heyn avec Acaulon fontiquerianum Casas & Sérgio (Pottiaceae).

Lors de travaux bryologiques menés dans la région de Sharon plane (Israël), une colonie d'*Acaulon* Müll. Hal. a été découverte. Les plantes ont montré des affinités morphologiques à la fois avec *A. longifolium* Herrnst. & Heyn et *A. fontiquerianum* Casas & Sérgio en fonction des flores utilisées pour leur identification, ce qui a contesté leur reconnaissance en tant qu'espèce distincte. Afin de résoudre cette énigme taxonomique, nous avons effectué une caractérisation morphologique détaillée des deux espèces sur la base d'échantillons représentatifs. L'étude micromorphologique des traits végétatifs, des sporophytes et des spores a révélé un grand chevauchement des gammes de valeur entre les deux espèces. Celles-ci ont montré une combinaison de caractères morphologiques, dont les feuilles largement incurvées avec des cellules lisses et les 4-6 rangées de cellules enflées sur la surface adaxiale de la nervure. La micromorphologie des spores a révélé le même modèle d'ornementation et la présence de 1-2 glomérules lamellaires sur la surface des spores. Les analyses multivariées et d'ordination basées sur des traits quantitatifs n'ont pas révélé de séparation significative entre les échantillons des deux espèces, s'opposant ainsi à leur reconnaissance en tant qu'espèces distinctes. Comme *A. fontiquerianum* a la priorité sur *A. longifolium*, ce dernier est donc considéré comme synonyme d'*A. fontiquerianum*. L'ajout de nouvelles données chorologiques et d'une taxonomie modifiée montre qu'*A. fontiquerianum* a une surface de répartition s'étendant des îles Canaries au bassin méditerranéen oriental. Cependant, le modèle dispersé suggère que sa distribution est largement incomplète en raison de la petite taille des plantes et de leur nature éphémère.

INTRODUCTION

Acaulon Müll. Hal. is a taxonomically challenging genus of the Pottiaceae whose representatives are rarely reported. Species of *Acaulon* inhabit open bare, often disturbed, soil in seasonally wet habitats that remain frequently unexplored but where they can be locally abundant (Sérgio *et al.* 1993). However, they are comparatively less collected because of the tiny size of the plants and their ephemeral life cycle (Kirmaci & Erdag 2014).

Despite its global rarity, the genus *Acaulon* is distributed in all continents except Antarctica, with much of its diversity being represented in areas of Mediterranean-type climate of Australia, northern and southern Africa, North America and Europe (Stone 1989; Sérgio *et al.* 1993). It is widespread in the Mediterranean region, where it is represented by eight species, six of which have been reported from Europe (Ros *et al.* 2013; Hodgetts *et al.* 2020). Two species have been described comparatively more recently, *A. fontiquerianum* Casas & Sérgio (Casas & Sérgio 1990) and *A. longifolium* Herrnst. & Heyn (Herrnstadt & Heyn 1999). *Acaulon fontiquerianum* was described from mainland Spain, where most of its known populations occur (Brugués *et al.* 2018). Despite its rarity it has been reported from scattered localities in six Mediterranean countries (Ros *et al.* 2013; Hodgetts & Lockhart 2020). On the other hand, *A. longifolium* has been less often reported (Herrnstadt *et al.* 2005) and is considered endemic to Israel. These two species share the presence of enlarged, swollen cells over the adaxial surface of the nerve, a distinctive trait that separates them from all other Mediterranean species and one that is also uncommon in the whole genus (*A. recurvatum* Magill, a third species with papillose cells, is endemic to South Africa, Magill 1981). This trait suggests a close morphologi-

cal relationship or even conspecificity of *A. fontiquerianum* and *A. longifolium*. Unfortunately, although the former was described almost a decade earlier, *A. fontiquerianum* was not compared to *A. longifolium* in the description of the latter (Herrnstadt & Heyn 1999). In the original description, it was compared only to three other Mediterranean *Acaulon* which do not show inflated cells on the adaxial part of the nerve and thus interpreted as a new species. Subsequent studies did not address the potential similarity of these two species (Herrnstadt *et al.* 2005).

During bryological work conducted in the Sharon plane region (Central-Western Israel), a colony of *Acaulon* plants was found. Upon microscopic examination, and based on the local flora, the plants presented characters which suggested they belonged to *A. longifolium* (Herrnstadt *et al.* 2005). However, consultation of other Mediterranean floras keyed the plants to *A. fontiquerianum*. This conflict raised reservations about the taxonomic distinction of this species pair. Thus, the aim of this study is to contribute to a better understanding of the taxonomical relationship between *A. longifolium* and *A. fontiquerianum* based on a thorough study of morphological traits of representative samples.

MATERIAL AND METHODS

SAMPLED MATERIALS

Plant materials used in this study consisted of six herbarium vouchers of *Acaulon longifolium* and ten of *A. fontiquerianum*, obtained from the Hebrew University of Jerusalem herbarium (HUJ, five vouchers), Museu Nacional de História Natural, Universidade de Lisboa herbarium (LISU, six vouchers), and

VAL-Briof (five vouchers), as well as fresh field collections. The herbarium material included type specimens of *Acaulon fontiquerianum* (LISU 153741) and *A. longifolium* (HUJ 900406, 900408).

LIGHT AND SCANNING ELECTRON MICROSCOPY ANALYSES
Measurements of vegetative and spore characters were taken using the interactive measurement module of Leica Application Suite (LAS) v. 3.8 (Leica Microsystems, Barcelona, Spain) calibrated to the nearest 0.01 µm on digital images. All measurements were taken through a DMLB 100S light microscope (Leica). A DFC425 digital camera (Leica) was used for producing high resolution images. For each population, 10 individuals were measured for all 11 qualitative and 18 quantitative traits considered (Table 1). Quantitative morphological traits were scored from a total of five populations ($N = 50$ plants) of *A. fontiquerianum* (LISU 269143, VAL-Briof. 7456, 11274, 11873 and 11874), and from three populations ($N = 30$ plants) of *A. longifolium* (HUJ 900405, 900406 and VAL-Briof. 12140).

Scanning Electron Microscopy (SEM) was used to study spore micromorphology. For this purpose, mature spores were mounted directly on stubs using double-sided adhesive tape and coated with gold/palladium in a BIORAD SC-500 ion sputtering coater. Morphological observations were carried out in a Hitachi S-4800 field emission scanning electron microscope (SEM) at the University of Valencia (SCSIE-UV), using an accelerating voltage of 10Kv. Nomenclature of spore characters follows Casas *et al.* (1990).

STATISTICAL ANALYSES

Statistical analyses were aimed at revealing whether morphological variation was consistent with the two currently recognized species of *Acaulon* and if so, at identifying the most informative set of morphological characters for their differentiation. Simple statistical descriptors of the within- and between-species morphological diversity (mean, range) were calculated for all measured characters (Table 1). Quantitative gametophytic, sporophytic and spore traits were further used for producing Factorial Correspondence Analyses (FCA) which were carried out on an individual-variable basis in order to estimate the contribution of the different quantitative traits scored to the morphological differentiation within and among species. Two dimensional plots resulting from the representation of the individual sample scores of two regression factors were constructed. All statistical analyses were conducted using SPSS v. 26.0.

RESULTS

The collected materials were fertile and allowed a full morphological characterisation of the new Israeli population of *Acaulon* (Figs 1, 2A-C). According to the morphological characters, these plants could be identified either as *A. longifolium* according to the Israel bryophyte flora (Herrnstadt *et al.* 2005) or as *A. fontiquerianum* following bryophyte

floras from elsewhere covering the Mediterranean regions (i.e., Guerra *et al.* 2006).

The measurement of vegetative, sporophytic and spore traits revealed the large overlap of range values between both species (Table 1). The same applied to qualitative traits which all were homomorphous (Table 1). Both species showed broadly incurved leaves with smooth cells with 4-6 rows of inflated cells on the adaxial surface of the nerve (Fig. 1). Spore micromorphology revealed the same ornamentation processes with spore surface densely covered with a mixture of acute baculae and baculae branched distally with dentate-spinose processes (Fig. 2C, E). Both species presented lamellar glomeruli with dentate-spinose margins (Fig. 2A, B, D, F-H).

In the factorial analysis, considering the whole set of 14 quantitative morphological characters, the first and second factorial functions accounted for only 34.85% of the total variance. The 2D plot showed samples of *A. fontiquerianum* were spread along the x-axis, indicating substantial morphological variation, intermingling with samples of *A. longifolium* in the left side of the plot (Fig. 3). Generally, samples with smaller values for the morphological traits measured clustered on the left side of the plot whereas samples with larger values clustered to the right; however, both extremes of the plot were connected by a large number of intergrading samples (Fig. 3). In the second factorial function (y-axis) samples from both species spread along positive and negative sides of the axis and thus contributed little to the separation of the two species. The combination of the two most informative factorial functions revealed a large overlap area of samples of *A. longifolium* with *A. fontiquerianum* (Fig. 3) with no clear separation.

DISCUSSION

TAXONOMIC IDENTITY OF *ACAULON LONGIFOLIUM*

The genus *Acaulon* has been the subject of some taxonomic studies during the past decades that have enlarged our understanding of its diversity in different areas of the world (Stone 1976, 1988, 1989; Brugués & Crum 1984; Casas *et al.* 1986; Casas & Sérgio 1990). Particular studies have been performed in search of additional spore micromorphological characters to assist the establishment of taxonomic boundaries (i.e., Casas *et al.* 1990), while others have revealed the insufficient morphological characterization of species since their description, which have led to obscure the distribution area (Sérgio 1992). The most recent addition of an *Acaulon* species to the Mediterranean bryoflora was made by Herrnstadt & Heyn (1999) with the description of *A. longifolium*. This species shows very different morphological traits to the known Israeli species at that time, which in the view of the authors justified its publication as a new species. Notwithstanding, they failed to compare it with *A. fontiquerianum*, a mostly western Mediterranean species which was described almost a decade earlier (Casas & Sérgio 1990).

The examination of the morphological variation of quantitative and qualitative traits scored from the gametophyte, sporophyte and spores between *A. fontiquerianum* and *A. longifolium*

TABLE 1. — Summary of the morphological characters studied in *Acaulon fontquierianum* Casas & Sérgio and *A. longifolium* Herrnst. & Heyn. For quantitative characters, average and range values, in parentheses, are given. *Bibliographic data.

folium show both extensive overlap of value ranges for quantitative traits measured, and homomorphy for qualitative traits scored (Table 1; Fig. 2). It is noteworthy to indicate that SEM micromorphological analysis of spores also revealed the same ornamentation pattern between *A. longifolium* (Fig. 2A-F) and *A. fontquierianum* (Fig. 2G-H) and the presence of 1-2 lamellar glomeruli on the spore surface. This latter trait has been consistently observed throughout its distribution range and has been considered diagnostic of *A. fontquierianum* (Casas & Sérgio 1990; Casas *et al.* 1990; Sérgio *et al.* 1993; Lo Giudice 1995; Cogoni & Scrugli 2000).

The reproductive system of *A. fontquierianum* remains unclear, as for most of its range no data have been provided. However, the species has been reported as autoicous (Casas & Sérgio 1990), rhizaoutoicous (Cano *et al.* 2012), and has been observed in one Portuguese and one Spanish population as paroicous, whereas *A. longifolium* has been reported as dioicous (Herrnstadt & Heyn 1999). Lack of availability of suitable material precluded the reassessment of the reproductive system for most of the materials studied, including those of *A. longifolium*. Thus, it remains ambiguous whether previous studies have determined correctly that the species are reproductively polymorphic, or whether this is due to inaccurate assessments of the reproductive system.

Multivariate analyses based on quantitative traits and ordination of samples in a bidimensional space did not reveal a neat separation among samples of the two species (Fig. 3).

The diffuse clustering, even for the more intensively sampled *A. fontquierianum*, may indicate a strong effect of environmental variation on quantitative morphological traits. Although both extremes of the distribution ranges have been sampled for this study, thus covering a significant part of the climatic variation of the distribution range of the species, still no clear differentiation was obtained. Therefore, our analyses oppose the recognition of *A. fontquierianum* and *A. longifolium* as separate species.

As *A. fontquierianum* was validly described earlier, this name has priority over *A. longifolium*. Therefore, the following synonymy is proposed:

Family POTTIACEAE Hampe
Genus *Acaulon* Müll. Hal.

Acaulon fontquierianum Casas & Sérgio

Cryptogamie, Bryologie, Lichénologie 11: 61 (1990).

TYPE. — Spain, Hispania, Cabo de Gata (Almería), Umbría del Cambrónero, UTM 30SWF77, suelo al borde de *Zizyphus lotus*, 100 m a.s.l., C. Casas, 23.III.1972 (holo-, BCB[BCB24529]; iso-, PC[PC0026212], LISU[LISU153741!], MUB[MUB3649], BM[BM000867535])

Acaulon longifolium Herrnst. & Heyn., *Nova Hedwigia* 69: 229, (1999) **syn. nov.**

DESCRIPTION

An updated description of *A. fontquierianum*, integrating the morphological variation from *A. longifolium* specimens studied is presented here:

Plants gregarious, bulbiform, light green becoming light brown with age, to 3.0 mm high including the leaf aristae; leaves 6-13 per plant, imbricate, incurved, oblong-ovate, concave, (1.2)-1.8(-2.4) × (0.-)0.8(-1.5) mm, outer leaves smaller, margins entire, recurved near the apex; leaf apex acute. Nerve excurrent in a concolorous, flexuose arista (113.2-)234.8(-406.9) µm long, in cross section with abaxial stereids in 2-3 rows; euricists absent, 1-2 hydroids sometimes present; adaxial surface of the nerve with (2-)4(-5) rows of smooth, inflated, (11.3-)17.3(-28.1) × (9.7-)16.1(-25.7) µm, cells, with cell walls thinner than those of cells from lamina.

Cells of lamina smooth, in cross-section with abaxial walls thicker than adaxial ones; basal cells rectangular (45.8-)70.1 (-108.1) × (11.7-)19.9(-32.7) µm; median cells, rectangular, subquadrate, polygonal to rhomboidal, (12.6-)21.2(-35.9) × (8.7-)14.6(-23.5) µm.

Paroicous, dioicous, autoicous or rhizautoicous. Seta straight, (85.7-)175.2(-334.3) µm. Capsule brown, sub-spherical to ovoid, cleistocarpous, (424.3-)657.0(-988.0) × (345.0-)574.0(-881.75) µm, shortly apiculate. Calyptra conical, mitrate, to 634.7 × 343.7 µm. Spores orange to brownish, rounded in shape, (19.1-)23.2(-27.5) × (15.2-)21.1(-31.1) µm, finely granulose at LM. Spore ornamentation at SEM densely baculate, baculae acute to branched-dentate distally; spores with 1-2 lamellar glomeruli with dentate-spinose margins.

HABITAT, ECOLOGY AND DISTRIBUTION

Species of *Acaulon* are common elements of bryophyte communities growing on bare, often disturbed, soil with seasonal fluctuation of soil humidity. In such situations they are usually associated with many other ephemeral Pottiaceae, Bryaceae and Ricciaceae. Throughout its distribution range *A. fontquierianum* has been reported from a variety of soil types (Sérgio *et al.* 1993), including volcanic, granitic, sandy and red clay (*terra rossa*), generally characterized by neutral to acidic pH. It also spans a large altitudinal range from almost sea level (Cogoni & Scrugli 2000) to 2100 m a.s.l. (Kirmaci & Erdağ 2014); however, the majority of the populations occur at low to moderate altitudes <100-1000 m a.s.l., and not far from the sea coast. In Israel, three out of the five locations where this species has been collected occur in areas as low as 45-55 m a.s.l. and at 5-10 km distance from the Mediterranean shore, and one (Jerusalem) at about 700 m a.s.l (D. Melamed, personal observation). Regarding the new population from the Ilanot Forest, a plantation of *Eucalyptus* sp., the plants were growing on exposed wet sandy soil, together with *Microbryum* sp. and *Tortula acaulon* (With.) R.H. Zander.

Acaulon fontquierianum has been confirmed previously from five Mediterranean countries (Fig. 4): France, including Corsica (Sérgio *et al.* 1993), Italian islands of Sardinia (Cogoni & Scrugli 2000) and Sicily (Lo Giudice 1995); Portugal (Sérgio *et al.* 1993, 2013, plus five additional populations newly reported in this study), Spain (Casas & Sérgio 1990; Casas *et al.* 1990; García-Zamora *et al.* 1998, 1999; Guerra *et al.* 2010; Ros & Werner 2010; Segarra-Moragues & Puche 2016; Brugués *et al.* 2018), including the Canary Islands (Dirkse *et al.* 1993) and Turkey (Kirmaci & Erdağ 2014; Ağcagil *et al.* 2020). A previous report from Morocco by (Cano *et al.* 2002) needs confirmation, as it was based on immature specimens – however, the plants show the characteristic inflated cells of *A. fontquierianum* on the adaxial side of the nerve supporting its possible occurrence in North Africa (Cano *et al.* 2002). In conclusion, the results from this study, based on the taxonomic reassessment of previous records and a recent collection of *A. longifolium*

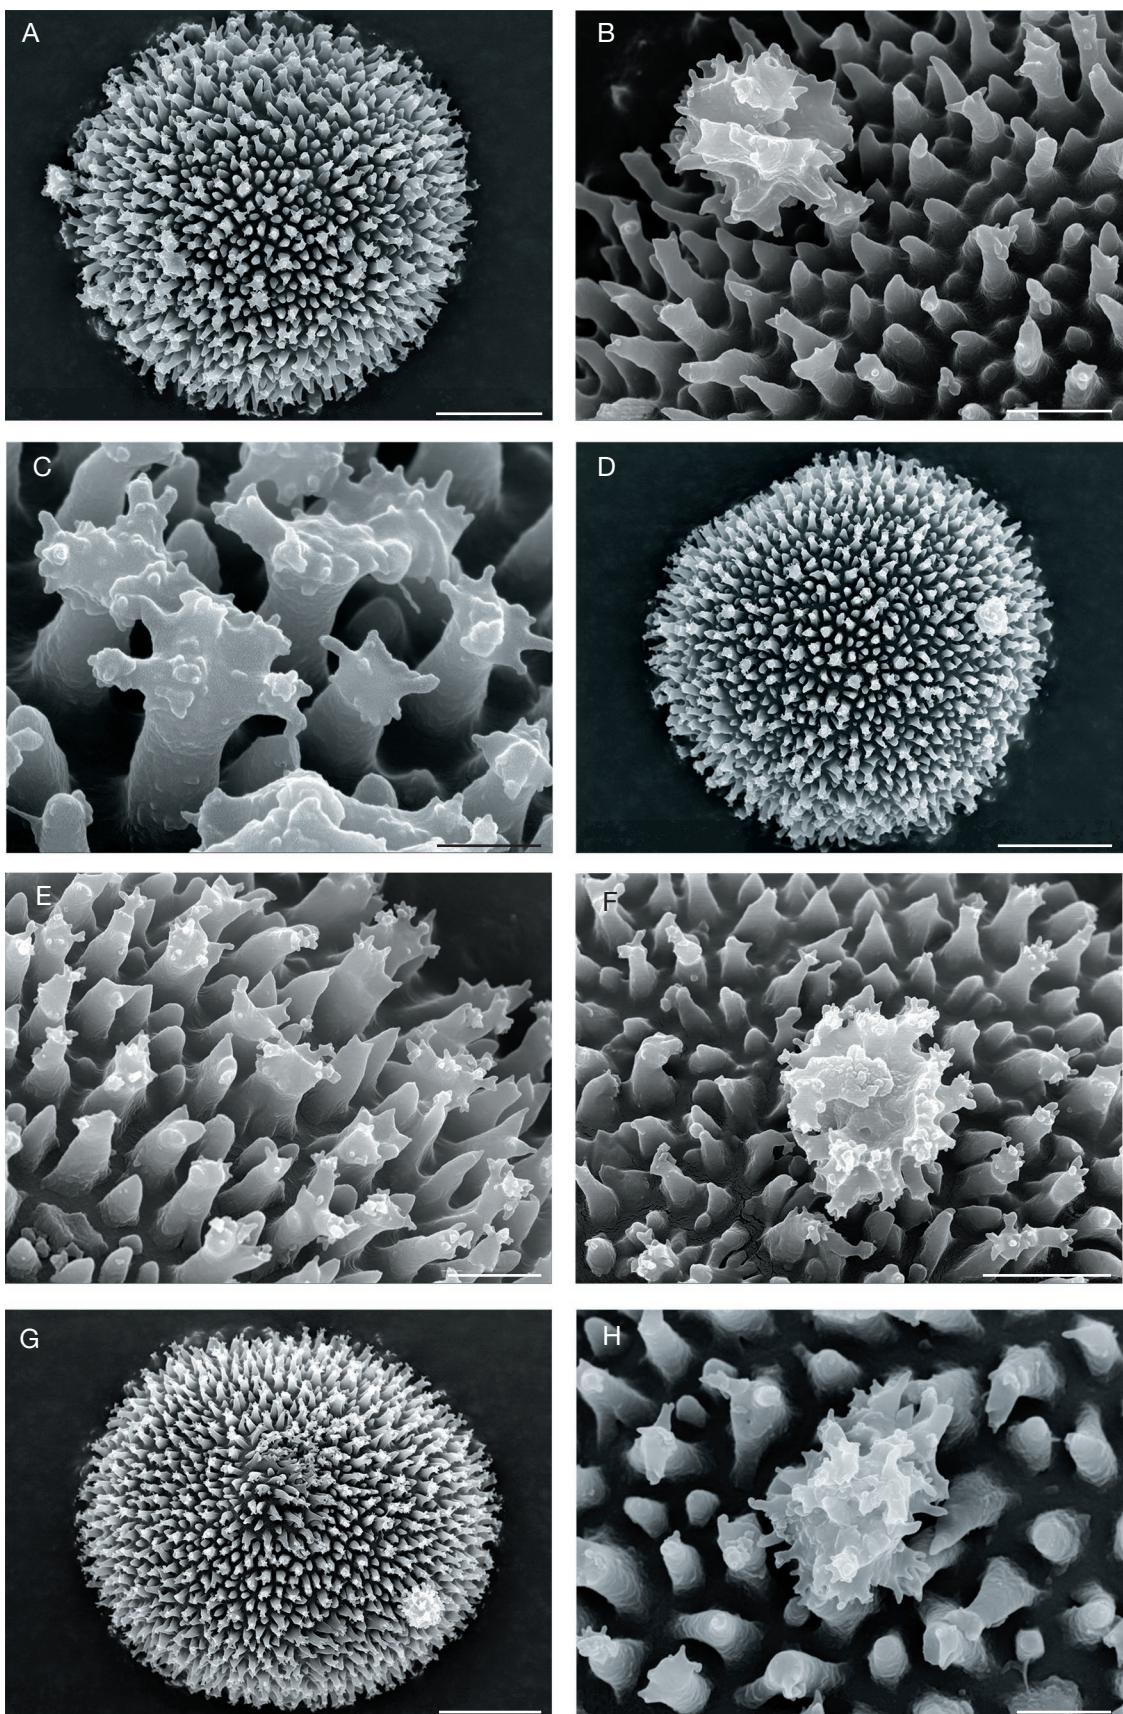

FIG. 2. — SEM images of spores of *Acaulon fontquierianum* Casas & Sérgio. **A, D, G**, general view; **B, F, H**, baculae and glomeruli; **C, E**, detail of branched-dentate baculae apices. (A-C from Israel, VAL-Briof. 12140; D-F from Israel, VAL-Briof. 12136; G from Spain, VAL-Briof. 11873; H from Portugal, LISU 269143, VAL-Briof. 11875). Scale bars: A, 5 µm; B, E, H, 1 µm; C, 0.5 µm; D, G, 6 µm; F, 2 µm.

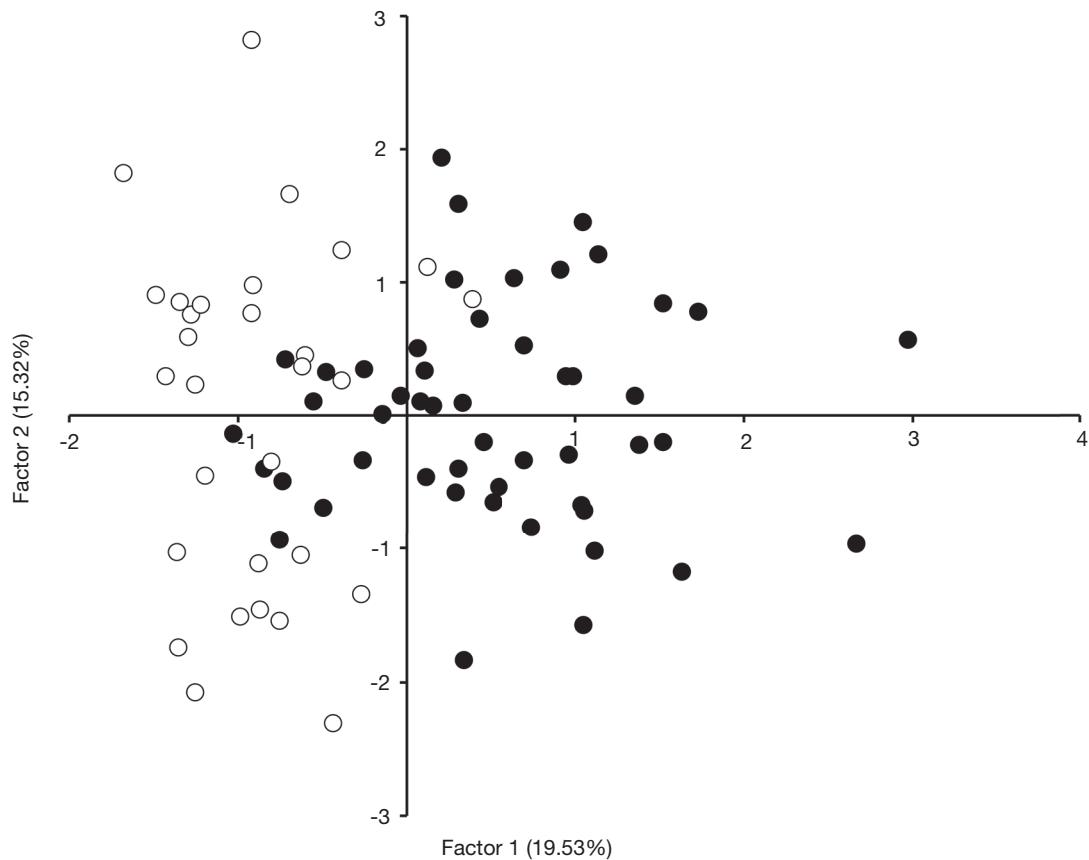

FIG. 3. — Factorial Correspondence Analysis (FCA) of *Acaulon fontquerianum* Casas & Sérgio (black dots) and *A. longifolium* (white dots) samples. The plot represents the space defined by the first (x axis) and second (y axis) regression factor scores and the percentage of variance explained by each factor is indicated in the corresponding axis of the plot.

(Herrnstadt & Heyn 1999; Herrnstadt *et al.* 2005), extend the distribution of *A. fontquerianum* to Israel.

CONSERVATION

Acaulon fontquerianum has been assigned to various IUCN threat categories in western Mediterranean countries. It has been assessed as Near Threatened (NT) for Spain (including Canary Islands) by Cano *et al.* (2012), although its threat category increased to Vulnerable (VU) when only mainland Spain and the Balearic Islands were considered (Brugués & González-Mancebo 2012; Cano *et al.* 2012; Albertos *et al.* 2018). A higher threat category (Critically Endangered, CR) was proposed for Portugal (Sérgio *et al.* 2013, 2014), whereas no assessment exists for other Mediterranean countries. Two of the Israel populations were collected from areas which are currently urbanized, thus increasing their chances of local extinction. A recent European-wide assessment of threatened bryophytes resulted in *A. fontquerianum* being listed as NT (Hodgetts *et al.* 2019; Sérgio & García 2019). Its global distribution pattern clearly shows a higher number of known populations in the western Mediterranean (Fig. 4) including several populations from the Canary Islands, although it is

unclear whether the apparent rarity towards the eastern Mediterranean is due to a less intense sampling effort. By contrast, it is apparently absent (or at least very rare) in North Africa (pending confirmation of the report from Cano *et al.* 2002). This may indicate that knowledge of the actual distribution area is incomplete, an issue exacerbated by the tiny size of the plants and their ephemeral nature in arid habitats. We therefore refrain from proposing changes to the IUCN threat category assigned to this moss until further field explorations are carried out in the eastern Mediterranean area.

Acknowledgements

We thank Dr Hagar Leschner, collection manager and Dr Neta Manela, scientific manager at the HUJ herbarium for sending duplicates of Israel specimens, M. J. Gil-López for his help in the preparation of the distribution map and Drs R. M. Ros and L. Sáez for helpful comments on an earlier version of the manuscript and R. D. Porley for the revision of the English. SEM images were taken at the Servei Central de Suport a la Investigació Experimental (SCSIE) from the University of Valencia whose technical staff helped with sample preparation for SEM.

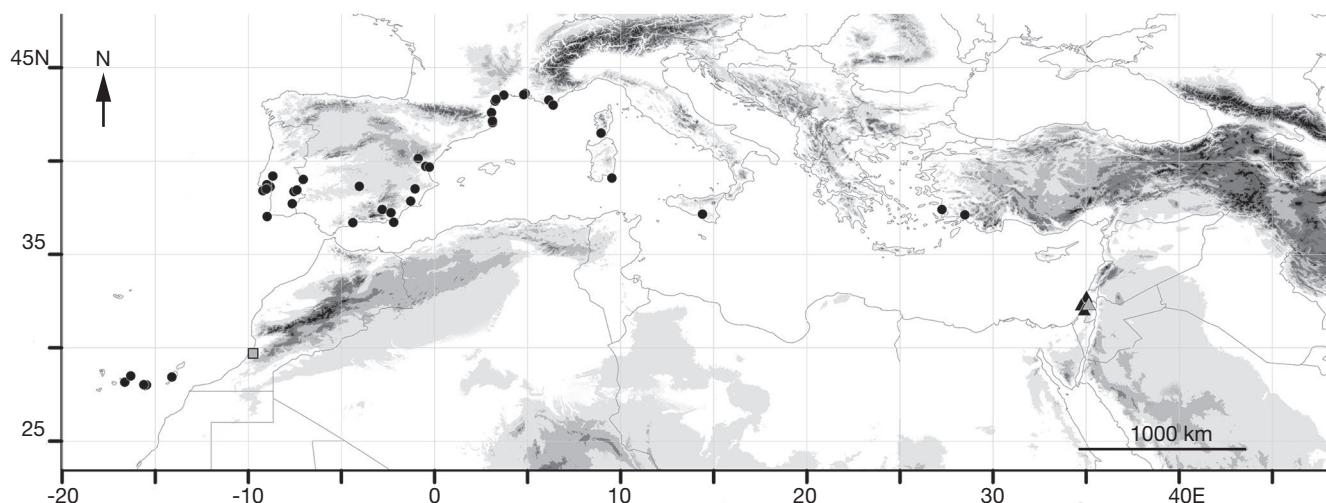

Fig. 4. — Known world distribution of *Acaulon fontquierianum* Casas & Sérgio based on published records and herbarium specimens. **Black dots** indicate populations initially ascribed to *A. fontquierianum*; a **grey square** indicates an unconfirmed Moroccan population of this species. Populations initially adscribed to *A. longifolium* Herrnst. & Heyn. and the new population are represented with **black** and **grey triangles**, respectively. Latitude and longitude numbers are indicated in degrees.
